## (54) APPARATUS FOR PROTECTING THE INFORMATION IN AN VIRTUAL MEMORY SYSTEM IN PROGRAMMED DATA PROCESSING APPARATUS

- (71) We, COMPAGNIE INTERNATIONALE POUR L'INFORMATIQUE C11-HONEYWELL-BULL, (formerly Compagnie Honeywell-Bull), a French Body Corporate, of 94 Avenue Gambetta, Paris 75020, France, do hereby declare the invention, for which we pray that a patent may be granted to us, and the method by which it is to be performed, to be particularly described in and by the following statement:—
- The present invention concerns apparatus for protecting the information in a virtual memory system in programmed data processing apparatus.
- Several schemes have been utilized in the past in order to protect information. Some of them are detailed by Robert M. Graham in a paper entitled "Protection in an Information Processing Utility", published in CACM (May 1968).
- This type of memory protection is inadequate for present day multiprogramming systems because there is no provision for gradations of privilege or gradations of accessability, and severely limits the control over access to information. There should be provisions for different access rights to the different types of information. A partial answer to this problem is found in the concept of a memory having a segment as the unit of information to which access is controlled (see Patent Application No. 21630/74, (Serial No. 1,465,344), filed on 15 May 1974). Varying degrees of access to each segment is possible by providing for different types of privileges attached to each segment such as master/slave, write/no-write and execute/non-execute. However, this method of protecting the privacy and integrity of information does not take into account the user of the information. Under this type of protection, privilege is not accorded the user but the information being protected. Hence a user if he has access at all to a segment has access similar to all other users who have access to the segment. David C. Evans and Jean Yves LeClerc in a paper entitled "Address Mapping and the Control of Access in an Interactive Computer," SJCC 1967, recognized the problem and attempted a solution. Evans and LeClerc said in that article p. 23, "The user of a computing system should be able to interact arbitrarily with the system, his own computing processes, and other users in a controlled manner. He should have access to a large information storage and retrieval system called the file system. The file system should allow access by all users to information in a way which permits selectively controlled privacy and security of information. A user should be able to partition his computation into semi-independent tasks having controlled communication and interaction among tasks. Such capability should reduce the human effort required to construct, debug, and modify programs and should make possible increased reliability of programs. The system should not arbitrarily limit the use of input/output equipment or limit input/output programming by the user". Evans and LeClerc proposed conditioning access rights on the procedure-in-execution. The segment, under their proposal, is still the unit of information to which access is controlled; however, a segment's access control attributes are recorded substantially in a user-name versus procedure tables whose entries are the access modes. Such a solution, however, has serious drawbacks. For one, the construction and updating of each segment's table of access control attributes presents a formidable task. For another, too many uses of the segment and event occurrences must be foreseen. To overcome this problem access control by procedure-set was suggested. Under this suggestion, related procedures are grouped into "sets of procedures" and access rights to segments is based on the identity of the set to which the procedure seeking access

belongs. This method alleviated the problem of constructing and updating each segment's voluminous tables of access control attributes, but introduced the problem of determining to which set a given procedure belonged, particularly when a procedure was or could be a number of many sets. This ambiguity in defining sets, and the possible transitions between sets makes the implementation of access control based on "sets of procedures" extremely difficult.

To overcome the difficulties encountered with the "set" technique a ring concept was developed. The ring concept groups the sets of procedures into rings that can unambiguously be ordered by increasing power or level of privilege. By assigning a collection of sets to a collection of concentric rings, and assigning numbers to each ring with the smallest ring having the smallest number and each succeeding larger ring having a progressively greater number, different levels of privilege can then be unambiguously assigned to the user of a segment. Under this concept the innermost ring having the smallest number assigned to it has the greatest privilege. Hence it can be postulated that users in the lowest ring number can access information having higher ring numbers, but users in a higher ring number cannot access information having lower ring numbers or can access information in a lower ring number only in a specified manner. This palpable change of power or level of privilege with a change in rings is a concept which overcomes the objections associated to a change of sets.

Multics (*Multiplexed Information and Computing Service*) is an operating system developed primarily by Massachusetts Institute of Technology, in cooperation with General Electric Co. and others which first utilized the ring theory of protection in software on a converted Honeywell 635 (Registered Trade Mark) computer and later on a Honeywell 645 (Registered Trade Mark) computer. The Multics philosophy utilizes 64 rings of protection numbered as rings 0—63 and is set forth generally in a paper entitled "Access Control to the Multics Virtual Memory" published by Honeywell Information Systems Inc. in the Multics Technical Papers, Order No. AG95, Rev. O. A more detailed description of Multics ring protection is to be found on chapter 4 of a book entitled "The Multics System: An Examination of its Structure", by Elliott I. Organick, published by MIT Press, and also in the Multics System Programmers Manual 1969, MIT Project MAC. Briefly, the Multics system does not utilize a "pure ring protection strategy" but rather employs the "ring bracket protection

strategy" wherein a user's access rights with respect to a given segment are encoded in an access-mode and a triple of ring number (r1, r2, r3) called the user's "ring brackets" for a given segment. A quotation from pages 137—139 from the Multics Technical Paper entitled, "Access Control to the Multics Virtual Memory" sets out the rules and conditions for using and changing rings.

This "ring protection concept" was first implemented with software techniques utilizing 64 separate rings. Subsequently an attempt was made to define a suitable hardware base for ring protection. The Honeywell 645 (Registered Trade Mark) computer represents a first such attempt. The Honeywell 645 (Registered Trade Mark) system differs from the "ringed hardware" concepts described supra in several respects which when taken together, add up to the fact that the Honeywell 645 (Registered Trade Mark) is a 2-ring rather than a 64-ring machine, and has in lieu of a "ring register", a master mode and a slave mode, which imparts greater power to the processor when in master mode than when in slave mode. "The access control field of the 645's SDW (segment descriptor word) contains no information about rings; in particular it does not contain ring brackets. It does, however, contain either:

- a) access-mode information possibly including either of the two descriptors; accessible in master mode only, master mode procedure;
- b) the specification of one of eight special 'directed' faults (traps) which is to occur whenever the segment descriptor word (SDW) is accessed.

"The procedure is only 'in master mode' when executing a procedure whose SDW indicates a 'master mode procedure'. The processor may enter master mode while executing a slave mode procedure by: faulting, taking an interrupt".

"The 645 processor's access control machinery interprets the SDW during the addressing cycle and causes the appropriate action to occur depending on the SDW and (usually) on the attempted access, as follows:

- a. If the SDW implies a particular "directed fault", then that fault occurs.

b. Otherwise, if the SDW does not permit the attempted access, the appropriate access violation fault occurs.

- c. Otherwise, the SDW permits the attempted access and the access is performed.

"When a fault occurs, the 645 enters master mode and transfers control to the

appropriate master mode fault handling procedure". (Access Control to the Multics Virtual Memory, supra pps. 157—158).

5 Another paper by Michael D. Schroeder and Jerome H. Saltzer entitled "A Hardware Architecture for Implementing Protection Rings" published in Communications of the ACM, March 1972 Vol. 15, No. 3, sets forth background and theory of ring protection and describes a hardware implementation of "ring protection".

10 Because the Multics and Honeywell 645 version of ring protection was implemented mainly in software, considerable operating system supervisor overhead was entailed particularly when calls to greater or lesser power were made by trapping to a supervisor procedure. What was required was an access control mechanism which had the functional capability to perform effectively its information protection function, was relatively simple in operation, was economic to build, operate and maintain, and did not restrict programming generality. The Honeywell 6000 (Registered Trade Mark) computer system met these requirements by implementing most of the ring protection mechanism in hardware. Hence special access checking logic, integrated with the segmented addressing hardware was provided to validate each virtual memory reference, and also some special instructions for changing the ring of execution. However certain portions of the ring system particularly outward calls and returns or calls to a lesser power and returns therefrom presented problems which required the ring protection function to be performed by transferring control to a supervisor. What is now needed are further improvements in hardware and techniques that will permit a full implementation of ring protection in hardware/firmware and will meet the criteria of functional capability, economy, simplicity and programming generality.

50 Accordingly the present invention has for an object to provide an improved computer ring protection mechanism.

55 Accordingly the present invention consists in an internally programmed data processing apparatus CPU having a virtual memory system, and being responsive to internally stored instruction words for processing information and having stored in said virtual memory system a plurality of different types of groups of information each information group-type associated with an address space bounded by a segment having adjustable bounds, and comprising means for protecting the information in said-virtual memory system from unauthorized users by restricting

accessability to the information in accordance to levels of privilege, said means comprising in combination with an access checking mechanism;

(a) first means arranged in operation to store in said virtual memory system at least one segment table comprising a plurality of segment descriptors with each segment descriptor being associated with a predetermined one of said segments and each segment descriptor having a predetermined format containing an access information element and a base address element in predetermined positions of said format, said base address element being used for locating in said virtual memory system the starting location of a selected one of said segments, and said access information element for specifying the minimum level of privilege required for a predetermined type of access that is permitted in a selected one of said segments;

(b) a plurality of second means having a predetermined format, communicating with said first means, arranged to store in a predetermined portion of said second means, a segment number SEG for identifying a segment table and the location of a segment descriptor within said segment table, said second means also being arranged to store in a predetermined other portion of said second means, an offset address within the segment identified by said segment descriptor said offset address locating from said segment base the first byte of a word within said segment;

(c) third means responsive to an address syllable element of an instruction being executed for addressing one of said plurality of second means;

(d) fourth means arranged to store a displacement from said address syllable;

(e) fifth means, communicating with said first, second, third and fourth means, arranged to add the displacement D and said base address to said offset; and,

(f) sixth means responsive to said access information element in a selected one of said segment descriptors, restricting the accessability to the segment associated with said selected one of said segment descriptors in accordance to the level of privilege and the type of access specified in said access information element, wherein each group-type of information is associated with a predetermined ring number indicative of a level of privilege said level of privilege decreasing as the associated ring number increases comprising means for determining the maximum effective address ring number EAR (i.e. minimum level of privilege) of a selected process to access a selected group of information, said means comprising:

(a) first means to store first information indicating the maximum ring number RD (i.e. minimum level of privilege) required to read information from said selected group;

(b) second means to store second information indicating the maximum ring number WR (i.e. minimum level of privilege) required to write information into said selected group;

(c) third means to store third information indicating the maximum ring number MAXR (i.e. minimum level of privilege) required to process information from said selected group; and,

(d) fourth means communicating with said first, second and third means, to determine the maximum of the contents of said first, second and third means whereby the effective address ring number EAR is generated.

The present invention, however, both as to organization and operation thereof may best be understood by reference to the following description which is given by way of example in conjunction with the accompanying drawings in which:

Figure 17 is a flow chart of the Exit Instruction.

As previously discussed the ring concept of information protection was originated on MULTICS and implemented on various Honeywell (Registered Trade Mark) Computer Systems. The original MULTICS concept required 64 rings or level of privilege and later implementation had the equivalent of two rings on the Honeywell 645 and 8 rings on the Honeywell 6000 (Registered Trade Mark). The embodiment described herein groups data and procedure segments in the system into a hierarchy of 4 rings or classes. (Refer to Figure 2). The 4 rings or privilege levels are identified by integers 0—3; each ring represents a level of privilege in the system with level 0 having the most privilege and level 3 the least. Level 0 is known as the inner ring and level 3 as the outer ring. The basic notion as previously discussed is that a procedure belonging to an inner ring has free access to data in an outer ring. Conversely a procedure in an outer ring cannot access data in an inner ring without incurring a protection violation exception. Transfer of control among procedures is monitored by a protection mechanism such that a procedure execution in an outer ring cannot directly branch to a procedure in an inner ring. This type of control transfer is possible only by execution of a special "procedure-call" instruction. This instruction is protected against misuse in a number of ways. First, a gating mechanism is available to ensure that procedures are entered only at planned entry points called gates when crossing rings. The segment descriptor of such a procedure contains a gate bit indicating that procedures in this segment can be entered only via gates; information regarding these gates is contained at the beginning of the segment and is used by the hardware to cause entry at a legal entry-point. The procedure itself must then verify (in a way which, of necessity depends on the function of the procedure) that it is being legitimately called. A further hardware protection mechanism is available in the case that the calling procedure supplies an address as a parameter; it is then possible that the more privileged procedure would invalidly modify information at this address which the less privileged caller could not have done, since the ring mechanism would have denied him access; an address validation instruction is available to avoid this possibility.

An important convention is required

here in order to protect the procedure call mechanism. This states that it is not in general permissible to use this mechanism to call a procedure in a less privileged ring and return to the more privileged one. This restriction is necessary since there is no assurance that the procedure in the higher ring will, in fact, return; that it will not, accidentally or maliciously, destroy information that the more privileged procedure is relying upon; or that it will not, accidentally or maliciously, violate the security of the stack (see GLOSSARY for definition). Any of these could lead to unpredictable results and crash the system.

The level of privilege are quite independent of the process control mechanism and there is no notion here of privileged and non-privileged processes as in the IBM system 360 (Registered Trade Mark). Instead the same process can execute procedures at different levels of privilege (rings) subject to the restrictions imposed by the ring mechanism. In this sense the ring mechanism can be viewed as a method for subdividing the total address space assigned to a process according to level of privilege.

The ring mechanism defined herein permits the same segment to belong to up to 3 different rings at the same time i.e. there are 3 ring numbers in each segment descriptor, one for each type of possible access. Thus the same segment can be in ring one with respect to "write" access, ring two with respect to "execute" access and ring three with respect to "read" access. One obvious use for this is in the case of a procedure segment which can be written only by ring zero (perhaps the loader) but can be executed in ring three.

Of the four available rings, two are allocated to the operating system and two to users. Ring zero, the most privileged ring, is restricted to those operating system segments which are critical to the operation of the whole system. These segments form the hard core whose correctness at all times is vital to avoid disaster. Included would be the system information base, those procedures dealing with the organisation of physical memory or the initiation of physical data transfer operations, and the mechanisms which make the system function, like the "exception supervisor, the scheduler, and the resource management".

Ring one contains a much greater volume of operating system segments whose failure would not lead to catastrophe but would allow recovery. Included herein are the language translators, data and message management, and job and process management. Through the availability of two rings for the operating system, the

problem of maintaining system integrity is made more tractable, since the smaller hard core which is critical is isolated and can be most carefully protected.

Rings two and three are available to the user to assign according to his requirement. Two important possibilities are debugging and proprietary packages. Programs being debugged may be assigned to ring two while checked out programs and data with which they work may be in ring two; in this way the effect of errors may be localized. Proprietary programs may be protected from their users by being placed in ring two while the latter occupy ring three. In these and other ways, these two rings may be flexibly used in applications.

#### The General Rules of the Ring System

1. A procedure in an inner ring such as ring 2 on Figure 2 has free access to data in an outer ring such as ring 3 and a legal access (arrow 201) results. Conversely a procedure in an outer ring such as ring 3 cannot access data in an inner ring such as ring 2 and an attempt to do so results in an illegal access (arrow 202).

2. A procedure in an outer ring such as ring 3 can branch to an inner ring such as ring 1 via gate 204 which results in a legal branch 203, but a procedure operating in an inner ring such as ring 2 may not branch to an outer ring such as ring 3.

3. Each segment containing data is assigned 2 ring values, one for read (RD) and one for write (WR). These ring values specify the maximum ring value in which a procedure may execute when accessing the data in either the read or write mode.

Each time a procedure instruction is executed, the procedure's ring number (effective address ring, EAR) is checked against the ring numbers assigned to the segment containing the referenced data. The EAR is the maximum number of process ring numbers in the processor instruction counter (see later description) and all ring numbers in base registers and data descriptors found in the addressing path. Access to the data is granted or denied based on a comparison of the ring numbers. For example, if a system table exists in a segment having a maximum read/ring value of 3 and a maximum write/ring value of 1, then a user procedure executing in ring 3 may read the table but may not update the table by writing therein.

#### Procedure Calls and the Stack Mechanism:

The procedure call and stack mechanism is an apparatus being described herein. Procedure calls are used to pass from one procedure to another; to allow user procedures to employ operating system services; and to achieve a modular

structure within the operating system. A procedure call is effected by instructions and a hardware recognized entity called a stack.

5 A stack is a mechanism that accepts, stores and allows retrieval of data on a last-in-first-out basis. Stacks reside in special segments called stack segments. A stack segment consists of a number of contiguous parts called stack frames which are dynamically allocated to each procedure. 10 The first stack frame is loaded into the low end of the segment and succeeding frames are loaded after it. The last frame loaded is considered the top of the stack. A T-register 114 (see Figure 1) locates the top of the stack for the currently active process. A virtual T-register exists in the process control block (PCB) of all other processes 20 in the system.

A stack frame consists of three areas: a work area in which to store variables, a save area in which to save the contents of registers, and a communications area in which to pass parameters between procedures. Prior to a procedure call, the user must specify those registers he wishes saved and he must load into the communications area the parameters to be 25 passed to the called procedure. When the call is made, the hardware saves the contents of the instruction counter and specified base registers to facilitate a return from the called procedure. 30

Each procedure call creates a stack frame within a stack segment and subsequent calls create additional frames. Each exit from one of these called procedures causes a stack frame to be 35 deleted from the stack. Thus, a history of calls is maintained which facilitates orderly returns. 40

To ensure protection between procedures executing in different rings, different stack segments are used. There is one stack segment corresponding to each protection ring per process. A process control block (PCB) contains three stack base words (SBW) which point to the start 45 of the stack segment for rings 0, 1 and 2 associated with the process. The ring 3 stack segment can never be entered by an inward call; therefore, its stack starting address is not required in the PCB. 50

55 The procedure call is used by users who have written their programs in a modular way to pass from one program module to another. It is used by user programs to avail themselves of operating system services. It is used by the operating system itself to achieve a responsive modular structure. 60 The procedure call as is described in the above referenced patent application is effected by hardware instructions and the hardware recognizable stack-mechanism. 65

The main requirements on a procedure call mechanism are:

1. Check the caller's right to call the caller;
2. Save the status of the caller which includes saving registers, instruction counter (for return), and other status bits;
3. Allow for the passing of parameters;
4. Determine valid entry point for the called procedure;
5. Make any necessary adjustments in the addressing mechanism;
6. Enter the new procedure.

When the called procedure terminates or exits, whatever was done in the call must be undone so that the status of the calling procedure is restored to what it was before the call. 70

As a preliminary to making a procedure call, the instruction PREPARE STACK is executed. This instruction causes those registers specified by the programmer in the instruction to be saved in the stack. It causes the status register (see Figure 1) to be saved, and provides the programmer with a pointer to parameter space which he may now load with information to be passed to the called procedure. 75

Another instruction ENTER PROCEDURE permits the procedure call via the following steps corresponding to the requirement specified above: 80

1. Ring checking—the caller's ring is checked to make sure that this ring may call the new procedure; the call must be to a smaller or equal ring number; and if ring crossing does occur the new procedure must be gated through a gate 204 of Figure 2. The new ring number will then be that of the called procedure. 85
2. The instruction counter is saved;
3. Base register 0 (see Figure 1) is made to point effectively to the parameters being passed;
4. The entry-point of the called procedure is obtained from a procedure descriptor whose address is contained in the ENTER PROCEDURE INSTRUCTION; 90
5. A point to linkage information is loaded in base register number 7. 95
6. The new procedure is entered by loading the new ring number and the address of the entry-point in the instruction counter. 100

The remainder of the current stack-frame is also available to the called procedure for storage of local variables. 105

When the called procedure wishes to return, it executes the instruction EXIT PROCEDURE. The registers and the instruction counter are then restored from their saving areas in the stack. 110

Referring to Figure 1 there is shown a block diagram and a computer hardware 115

120

125

130

system utilizing the invention. A main memory 101 is comprised of four modules of metal-oxide semi-conductor (MOS) memory. The four memory modules 1—4 are interfaced to the central processor unit 100 via the main store sequencer 102. The four main memory modules 1—4 are also interfaced to the peripheral subsystem such as magnetic tape units and disk drive units (not shown) via the main store sequencer 102 and the 10C (not shown). The main store sequencer gives the capability of providing access to and control of all four memory modules.

Operations of the CPU are controlled by a read only memory ROM, herein called the control store unit 110.

The control store interface adapter 109 communicates with the control store unit 110, the data management unit 106, the address control unit 107 and the arithmetic logic unit 112 for directing the operation of the control store memory. The control store interface adapter 109 includes logic for control store address modification, testing, error checking, and hardware address generation. Hardware address generation is utilized generally for developing the starting address of error sequencers or for the initialization sequence.

The buffer store memory 104 is utilized to store the most frequently used or most recently used information that is being processed by the CPU.

The data management unit 106 provides the interface between the CPU 100 and main memory 101 and/or buffer store memory 104. During a memory read operation, information may be retrieved from main memory or buffer store memory. It is the responsibility of the data management unit to recognize which unit contains the information and strobe the information into the CPU registers at the proper time. The data management unit also performs the masking during partial write operations.

The instruction fetch unit 108 which interfaces with the data management unit 106, the address control unit 107, the arithmetic and logic unit 112 and the control store unit 110 is responsible for keeping the CPU 100 supplied with instructions.

The address control unit 107 communicates with the instruction fetch unit 108, the buffer store directory 105, the main store sequencer 102, the arithmetic logic unit 112, the data management unit 106, and the control store unit 110 via the control store interface adapter 109. The address control unit 107 is responsible for all address development in the CPU.

Interfacing with the address control unit

107, the instruction fetch unit 108 and the control store unit 110 is the arithmetic logic unit 112 which is the primary work area of the CPU 100. Its primary function is to perform the arithmetic operations and data manipulations required of the CPU.

Associated with the arithmetic logic unit 112 and the control store unit 110 is the local store unit 111 which typically is comprised of a 256-location (32 bits per location) solid state memory and the selection and read/write logic for the memory. The local store memory 111 is used to store CPU control information and maintain ability information. In addition, the local store memory 111 contains working locations which are primarily used for temporary storage of operands and partial results during data manipulation.

The central processing unit 100 typically contains 8 base registers (BR) 116 which are used in the process of address computation to define a segment number, an offset, and a ring number. The offset is a pointer within the segment and the ring number is used in the address validity calculation to determine access rights for a particular reference to a segment.

The instruction counter 118 communicates with the main memory local register (MLR) 103 and with the instruction fetch unit 108, and is a 32-bit register which contains the address of the next instruction, and the current ring number of the process (PRN). Also contained in the central processing unit is a T register 114 which also interfaces with the instruction fetch unit 108 and is typically a 32-bit register containing a segment number and a 16-bit or 22-bit positive integer defining the relative address of the top of the procedure stack. The status register 115 is an 8-bit register in the CPU which among other things contains the last ring number—i.e. the previous value of the process ring number (PRN).

The main memory 101 is addressed by the memory address register (MAR) 119, and the information addressed by (MAR) 119 is fetched and temporarily stored in the memory local register (MLR) 103.

Referring now to Figure 3 there is shown a flow diagram of the general rules for segmented address development shown in detail in the above mentioned copending patent application No. 21630/74, Serial No. 1,465,344. Figure 3 when read in conjunction with the above referenced patent application is self-explanatory. There is however one major difference between the address development as shown on Figure 3 to that of the above mentioned application and that is that in the address development of Figure 3 of the instant application as many as 16 levels of

indirection may be utilized in the address development whereas in the above referenced application the levels of indirection were limited to a maximum of two. This of course is a matter of choice with the designer and in no way alters the high level inventive concept.

Referring now to Figures 4A—4J, Figures 4A and 4B show the format of the instruction counter designated by reference numeral 118 on Figure 1. The instruction counter (IC) 118 is a 32-bit register which contains the address of the next instruction, and the current ring number of the process (PRN). Referring specifically to Figures 4A and 4B the TAG is a 2-bit field which corresponds to the TAG field of data descriptors shown and described in the above reference application entitled "Segmented Address Development". PRN is a 2-bit field which defines the current ring number of the process to be used in determination of access rights to main storage. SEG is typically either a 12-bit or a 6-bit field which defines the segment number where instructions are being executed. The OFFSET is typically either a 16-bit or a 22-bit field which defines the address of the instruction within the segment SEG.

Figures 4C—4F show the format of segment descriptors with Figures 4C and 4D showing the first and second word of a direct segment descriptor whereas Figures 4E and 4F show the first and second word of an indirect segment descriptor. Segment descriptors are two words long each word comprised of 32 bits. Referring to Figures 4C—4D which show the first and second word respectively of a direct segment descriptor, P is a presence bit. If P equals one, the segment defined by the segment descriptor is present in main storage. If P equals zero, the segment is not present and a reference to the segment descriptor causes a missing segment exception. All other fields in a segment descriptor have meaning only if P equals one. A is the availability bit. If A equals zero, the segment is unavailable (or locked) and a reference to the segment causes an unavailable segment exception. If A equals one, the segment is available (or unlocked, and can be accessed). I is the indirection bit. If I equals zero, the segment descriptor is direct. If I equals one, the segment descriptor is indirect. U is the used bit. If U equals zero, the segment has not been accessed. If U equals one, the segment has been accessed. U is set equal to one by any segment access. W is the written bit. If W equals zero, no write operation has been performed on the segment. If W equals one, a WRITE operation has been performed on the segment. W is set to one by any WRITE

operation. GS is the gating-semaphore bits. When the procedure call mechanism referred to above requires that the segment be a gating segment or when the process communication mechanism (not shown) requires that the segment be a segment descriptor segment (SD) the GS bits are examined. To be a valid gating segment, the GS bits must have the value 10. To be a valid SD segment, the GS bits must have the value 01. If a gating or SD segment is not required, these bits are ignored. The BASE is a 24-bit field which defines the absolute address in quadruple words of the first byte of the segment. This field is multiplied by 16 to compute the byte address of the segment base. The SIZE is a field which is used to compute the segment size. If the segment table number, subsequently referred to as STN, is greater or equal to zero but less than or equal to six, the SIZE field is 18 bits long. The STN is a field indicating the segment table entry STE for selecting a segment descriptor. If the STN is greater than or equal to 8 but less than or equal to 15, the SIZE field is 12 bits long. The number of bytes in the segment is equal to 16 times (SIZE+1). If SIZE equals zero, the segment size is 16 bytes. RD is the read access field. This is a 2-bit field which specifies the maximum EAR (effective address ring number) for which a read operation is permitted on the segment. (A procedure is always permitted to read its own segment if EAR equals PRN). WR is the write access field. This is a 2-bit field which specifies the maximum EAR for which a write operation is permitted on the segment and the minimum PRN at which the segment may be executed. MAXR is the maximum ring number. This is a 2-bit field which specifies the maximum PRN at which the segment may be executed. WP is the write permission bit. This bit indicates whether a WRITE operation may be performed on the segment. If WP equals zero, no WRITE operation may be performed. If WP equals one, a WRITE operation may be performed if EAR is greater than or equal to zero but less than or equal to WR. EP is the execute permission bit. This bit specifies whether the segment may be executed. If EP equals zero, the segment may not be executed. If EP equals one, the segment may be executed at any PRN for which PRN is greater than or equal to WR but less than or equal to MAXR. MBZ is a special field which must be set to zero by software when the field is created, before its initial use by hardware.

Referring to Figures 4E—4F the definitions of the various fields are similar as above however word 0 includes a LOCATION field and word 1 includes a

RSU field. The LOCATION field is a 28-bit field which defines the absolute address of a direct segment descriptor. The value in the LOCATION field must be a multiple of 8.

5 The RSU field is a special field which is reserved for software use.

Figures 4G—4H show the format of the base registers (BR) which are used in the process of address computation to define a segment table number, a segment table entry number, an offset, and a ring number. There are typically 8 base registers as shown by reference numeral 116 on Figure 1. A base register is specified or identified as base register 0 through 7. The size of a base register is 32 bits long. The base register format of Figure 4G is utilized for small segment i.e. where STN is greater or equal to 8 but less than or equal to 15, whereas the format of base register of Figure 4H is utilized for large segments i.e. STN is greater or equal to zero but less than or equal to six. Referring to Figures 4G—4H, TAG is a 2-bit field which corresponds to the TAG of a data descriptor referenced previously. RING is a 2-bit field which contains the ring number associated with the segmented address for protection purposes. SEG is a field previously referred to, which identifies a segment described in a segment table. STN is the segment table number, and STE is the segment table entry number. OFFSET is a 16-bit field or a 22-bit field depending on segment table number, which defines a positive integer. The OFFSET is used in the process of address development as a pointer within a segment.

Referring to Figures 4I—4J there is shown the format of the T-register. The T-register is a 32-bit register containing a segment number and a 16-bit or 22-bit positive integer defining the relative address of the top of the procedure stack previously mentioned. The T-register is shown by reference numeral 114 on Figure 1. The various fields of the T-register have the same definition as described above.

Referring now to Figures 3 and 4A—4J a more defined description of absolute address calculation and access checking is made. In general absolute address calculation consists of fetching a segment descriptor specified by STN and STE and using the segment descriptors in four ways: access checking, computation of the absolute address, bound checking, and updating (U and W flags). As described in copending patent application No. 21630/74, (Serial No. 1,465,344) the absolute address may be direct or indirect and is derived by first deriving an effective address from STN, STE, and SRA (segment relative address). STN is extracted from bits 4 through 8 of the base register BR specified

in the address syllable of an instruction. If STN is 7, an out of segment table word array exception is generated. STE is extracted from the base register specified in the address syllable. If STN 4:4 (i.e., beginning at bit 4 and including the next 4 bits) is greater than or equal to zero or less than or equal to six, STE is in a base register bits 8 and 9. If STN 4:4 (i.e. 4 bits beginning at bit 4) is greater than or equal to 8 but less than or equal to 15, STE is in a base register BR bits 8 through 15. The segment relative address SRA for direct addressing is computed by adding the displacement in the address syllable; the offset of the base register BR; and the 32-bit contents of an index register, if specified in the address syllable. The sum of these three quantities is a 32-bit unsigned binary integer which must be less than the segment size appropriate to the segment STN, STE.

Indirect addressing is developed by fetching a data descriptor and developing an address from that descriptor. The effective address of the data descriptor is computed as in the direct addressing case with the exception that the index register contents are not used. In developing the address from the data descriptor the effective address may be computed by an indirection to segment ITS descriptor and an indirection to base ITBB descriptor. If the descriptor is ITS the STN and STE are extracted from the descriptor in the same manner as from a base register. SRA is computed by adding the displacement in the descriptor and the contents of an index register as specified in the syllable. If the descriptor is an ITBB descriptor then STN and STE are extracted from the base register specified in the BBR field (i.e. the base register implied by ITBB descriptor) of the descriptor as in direct addressing. SRA is computed by adding the displacement in the descriptor, the offset of the base register, and the contents of an index register is specified in the address syllable.

As shown on Figure 3 the indirection process may be extended up to 16 levels.

Every effective address contains protection information which is computed in address development and checks for access rights by the ring protection hardware of the absolute address calculation mechanism. The effective address contains protection information in the form of an effective address ring number EAR (see Figures 2J and 2K of above application No. 21630/74, (Serial No. 1,465,344). The EAR is computed from the base register ring number BRN and from the current process ring number PRN by taking the maximum ring number. In developing the EAR for indirect addressing

a somewhat more tedious but essentially similar procedure as indirect addressing is used. In indirect addressing the EAR for extraction of the first descriptor (EAR 1) is once again the maximum of the ring number from the base register specified in the address syllable and the current process ring number PRN in the instruction counter 115 of Figure 1 and stored in 00 register 512 of Figure 5. The EAR for extraction of the second descriptor (EAR 2), of multiple level indirection is the maximum of:

- a. EAR 1;
  - b. The ring number in the first descriptor if indirection is indirection to segment;
  - c. The ring number from a base register 116 utilized as a data base register BBR if the first descriptor is an indirection to segment descriptor ITBB.
- The EAR for extraction of the data of multiple level indirection is the maximum of:
- a. EAR 2;
  - b. The ring number in the second descriptor if it is an indirection segment descriptor ITS;
  - c. The ring number in one of the base registers utilized as a data base register BBR if the second descriptor is an indirection to base descriptor ITBB.

Referring now to Figures 5 and 6, the transfers and manipulation of the various type ring numbers will be described at the system level. Detailed logic block diagrams for effecting the transfers and operations of Figure 5 will be later described. Referring first to Figure 6 an associative memory 600 is utilized in segmented address development. The associative memory 600 comprises essentially a UAS associator 609 which has circuitry which includes associative memory cells, bit sense amplifiers and drivers, and word sense amplifiers and drivers (not shown). A word or any part of a word contained in UAS associator 609 may be read, compared to another word with a match or no match signal generated thereby, or be written either in whole or in a selected part of the associator 609. For example, US register 607 may contain a segment number which may also be in the associative memory 600. A comparison is made with UAS associator 609 and if a match is found a "hit" results. The match or "hit" signal is provided to encoder 610. The function of encoder 610 is to transform the "hit" signal on one of the match lines to a 4 bit address. Encoder 610 provides this 4 bit address to UAB associator buffer 611 so that the information contained in that particular location of UAB associator buffer 611 is selected. Information in UAB associator buffer 611 may be transferred to UV register 613 for temporary storage or

for transfer to QA or QB bus 614 and 615 respectively. By thus locating a prestored segment number of the associative memory 600 (which may have been placed there after a generation of an absolute address) regeneration of the same address is not necessary. In the drawing of Figure 6, UAB associator buffer 611 is shown as storing a first and second word of a segment descriptor; however other types of information may just as well be stored therein. This buffer 611 provides a function similar to that of buffer 104 in the more generalised diagram of Figure 1.

As mentioned supra the development of an absolute address of an operand from an effective address is disclosed in patent application No. 21630/74, (Serial No. 1,465,344). Briefly and with reference to Figure 6 any of 8 base registers 602 are addressed via UG and UH registers 603 and 604 respectively which contain base register addresses from an instruction address syllable or base register specified by the instruction formats. The base register 602 contain such information as TAG, base register ring number BRN, segment table number STN, segment table entry STE and OFFSET as shown or contained by base registers 1 and 2 of the group of base registers 602. Writing into the base registers is performed under micro-op control by UWB logic 601. For example it is shown that information from the UM register 502 of Figure 5 may be written into bit positions (2, 3) of a selected base register; also information from the QA bus may be written into the base registers and provisions are made to clear a selected base register i.e. write all zeroes. Reading out of any of the base registers is performed by UBR logic 605. In general the UBR logic 605 permits the appropriate base register to be strobed out onto bus QA or QB, or into UN register 608. Note that UN register 608 holds bits 8 through 31 of the base registers which is the OFFSET part of the segmented address. Moreover UBR logic 605 when addressed by an address contained in instruction buffer IB (not shown) reads out the segment number SEG (which is comprised of STN and STE) into US register 607 via UBS transfer logic 606. The comparison of the segment number SEG in US register 607 with the associative memory 600 may then be performed as previously described. It will be noted that bits (4—15) of QA bus 614 may also be read into or from US register 607. Similarly bits (8—31) from QA bus 614 may read into UN register 608. Also bits (9—11) of the US register 607 may be read into QA bus 614 as denoted by US (9—11) arrow (the arrows into various register and/or logic circuitry denote the source of data and that followed

by a number denote the bit numbers of that data).

Referring now to Figures 5 and 6, a 2-bit UP register 501 stores the current process ring number PRN. The current process ring numbers PRN is obtained from bits 2 and 3 of the instruction counter (118 or Figure 1) via bits IC (2—3) of the QA bus 614 of Figure 6. Bits IC (2—3) of QA bus 614 are transferred to 2-bit UV register 503 under control of a micro-operation UV9QA0. The micro-operations are obtained from micro-instructions in the control store unit 110. (On Figure 5 the dot surrounded by a circle indicates a micro-operation and the first two letters of the name of the micro-operation indicate the destination of the data to be transferred; the fourth and fifth letters indicate the source of the data transferred; the third character indicates whether a full or partial transfer is made with F indicating a full transfer while the sixth character indicates whether the signal doing the transferring is high or low with even numbers indicating a low signal and odd numbers indicating a high signal. As an example of the use of this convention bits 2 and 3 on QA bus indicating the tail of the arrow QA (2, 3) indicate PRN is the PRN process ring number that is being transferred under control of the micro-op UV9QA0 which says the transfer is made to register UV, is a partial transfer of the bus QA, and the source of the data is the bus QA, and is an unconditional transfer as indicated by the sixth character being 0. Transfer to UV register from QA bus source is unconditional. This 0 will be the corresponding seventh character in the logic file name of the subcommand UV9QA1φ. Once the process ring number PRN is transferred from the QA bus 614 to the UV register 503 another transfer takes place under control of the micro-operation UM9UV0 from UV register 503 to UM register 502. Finally another transfer takes place from UM register 502 to UP register 501 under control of a micro-operation UP9UM0.

Two bit register UM 502 is utilized to generate the effective address ring number EAR during ITS and ITBB (i.e. indirection to segment and indirection to base), (EAR=MAX (BRN, PRN, DRN/BBR (BRN) etc.) address formation for address syllable 1 and address syllable 2 type instruction format. The EAR is generated according to the rules previously enunciated by utilizing one or more tests shown in block 510 and the maximum of the ring number is obtained and stored in UM register 502 which stores the effective address ring number EAR (detailed logic or making the comparisons of block 510 are later shown and described in detail). The

UO register is used to save address syllable 1 effective address ring number EAR in the event the address syllable 2 is being utilized to extract EAR 2.

Two-bit UV register 503, and 2-bit UW register 504 is utilized mainly as storage for various ring numbers that are obtained from the outside of the ring checking hardware of Figure 5 and transferred or processed to other parts of the ring checking hardware. For example the base register ring number BRN is transferred from bit positions 2 and 3 of UBS transfer logic 606 to UV register 503 under control of the micro-operation UVFBS0; the maximum ring number MAXR of word 2 of the segment descriptor (also shown stored in bits 36 and 37 of UAB associator buffer 611) is transferred from UAB buffer 611 to UV register 503 under control of the micro-operation UVFAB1; also bits 34 and 35 of UAB buffer 611 which is the write ring number WR is transferred to UV register 503 under control of micro-operation UVFAB0. UW register 504 has similar transfers of other ring numbers from various parts of the system. For example bits 34 and 35 which are the write ring number WR of UAB buffer 611 may also be transferred to UW register 504 under control of micro-operation UWFAB1; bits 32 and 33, the read RD ring number of UAB buffer 611 may also be transferred to UW register 504 under control of micro-op UWFAB0; also bits 0 and 1 of QA bus 614 may be transferred to UW register 504 under control of micro-operation UW9QA0. Note also several transfer paths of UW register 504 into UV register 503 under control of the micro-operation UV9UW0; the transfer path of UV register 503 into UM register 502 under control of micro-operation UM9UV0; the transfer path of UM register 502 into UP register 501 under control of the micro-operation UP9UM0; the transfer path of UP register 501 into UM register 502 under control of micro-operation UM9UP0; the transfer path of UM register 502 into UO register 512 under control of micro-operation UO9UM0; and finally the transfer path of UO register 512 into UM register 502 under control of the micro-operation UM9UO0.

Briefly therefore UP register 501 holds the current process ring number PRN; UM register 502 and UO register 512 are utilized for transfer operations and also to generate the EAR; UV register 503 may shore for various purposes and at different times the current process ring number PRN, the base register ring number BRN, the maximum ring number MAXR, the write ring number WR, or the read ring number RD. UW register 504 may at various times hold the read ring number RD, the write ring

number WR, and bits 0 and 1 of bus QA. UMR 505 is logic, the details of which are shown on Figure 8d, which compares the contents of registers UM and UV and produces the greater of the two values in the registers and this value is stored in UM register 502 under micro-operation control UMFMR0. This is one way of generating the effective address ring number EAR. UMR logic 505 may also produce the greater value of the contents of register UP or of bits 2 and 3 of UBS logic 606. This is another method and/or additional step in generating the effective address ring number EAR. UMR logic 505 is also utilized to determine whether or not a write violation has occurred by transferring a write ring number WR into UV register 503 and then comparing the contents of the UM register 502 (holding EAR) with the contents of UV register 503 in order to determine which one has the greater contents. Since UM register 502 stores the effective address ring number EAR a comparison of the UM register and the UV register will indicate whether EAR is greater than WR or vice versa. If WP (i.e. write permission bit in the segment descriptor) is equal to 1 and if EAR lies in the range of  $0 \leq \text{EAR} \leq \text{WR}$  then a write operation may be performed into the segment. Note that UMR logic 505 may have inputs directly or indirectly from all registers 501—504, from other logic 506, 507 and also from UBS logic 606.

UWV logic 506 corresponds to the detail logic of Figure 8a. UWV logic 506 has inputs directly or indirectly from registers 501—504 and from logic 505, 507 respectively and generates an execute violation signal when a comparison of UW, UM and UV registers 504, 502, and 503 respectively indicates that the statements that the maximum ring number MAXR is greater or equal to the effective address ring number EAR, and that EAR is greater or equal to the write ring number WR are not true i.e. in order for a procedure to be able to execute in a given segment indicated by the effective address the maximum ring number MAXR must be greater or equal to the effective address ring number and the effective address ring number EAR must be equal or greater than the write ring number WR. UWV logic 506 also performs tests shown in block 510. Indications may be given that the contents of UW register is less than or equal to the contents of the UV register; the contents of the UM register is greater than or equal to the contents of the UV register; the contents of the UV register is equal to the contents of the UM register; the contents of the UV register is greater or equal to the contents of the UM register; and the

contents of the UM register is greater than the contents of the UW register. Of course when performing these tests different values of ring numbers may occupy the registers.

UEP logic 507 corresponds to the detail logic of Figure 8b. UEP logic 507 in combination with UWV logic 506 generates the read violation exception. However the read violation exception may be overridden if the effective address ring number EAR equals the current process ring number PRN, since a procedure is always permitted to read its own segment, and if the segment number of the procedure segment descriptor (not shown herein) and the segment number of the address syllable utilized in generation of the effective address are the same.

To illustrate the overriding of the read violation signal assume that the effective address read number EAR is greater than the read number RD which would generate a read violation high signal which would be applied as one input of AND gate 522. However the read violation exception signal may not be generated even though there is a read violation signal if the following two conditions exist:

1. The effective address ring number EAR is equal to the process ring number PRN; i.e. the contents of register UM is equal to the contents of the register UP; and,

2. The segment number contained in the address syllable of the segment in which a procedure desires to read is equal to the segment number of the procedure segment descriptor (not shown) of the current procedure in execution and this is indicated by setting a bit called a P bit and located as the thirteenth bit of UE register 650. (UE register 650 is a store for the contents of UAS associator 609 when a "hit" has resulted by a comparison of the contents of US register 607). Since this example assumes that EAR equals PRN, UEP logic 507 will apply a high signal to AND gate 520 as one input, and since it is also assumed that the segment number SEG of the address syllable of the segment being addressed is equal to the segment number SEG of the procedure segment descriptor (not shown) of the currently executing procedure, then the P bit of the procedure segment descriptor will be set and hence the other input applied to AND gate 520 will be high thus enabling AND gate 520; a high signal is therefore applied to the input of inverter 521 resulting in a low signal at the output of inverter 521 which low signal is then applied as another input of AND gate 522. Since there is a low signal to AND gate 522 no read violation exception signal can be generated by amplifier 523 even if

the third input signal applied to AND gate 522 is high.

To illustrate how a read violation signal is generated and not overridden, assume that the output of UEP logic 507 indicates that the contents of UM register is not equal to the contents of UP register. Then that input to AND gate 520 would be low and hence AND gate 520 would not be enabled and its output would be low and would be applied to the input of inverter 521. Since the input of inverter 521 is low its output would be high which would be applied as one input of AND gate 522. If also the effective address ring number EAR is greater than the read ring number RD (i.e. contents of UM register is greater than contents of UW register) that signal would be high and would be also applied to another input of AND gate 522. AND gate 522 has still a third input which must also be high in order to enable AND gate 522. This third input is high when AND gate 526 is enabled. Since AND gate 526 has one input terminal which is high when the 00 terminal of URVIF flop 524 is low, AND gate 526 is enabled by applying the micro-operation read violation interrogate signal AJERVA to one input terminal of AND gate 526 while the 00 terminal of URVIF flop 524 is low. Thus AND gate 522 will have all input terminals high, generating the read violation exception signal.

The execute violation exception is generated in two ways. It was seen earlier that an execute violation signal results when UWV logic 506 indicates that the inequalities WR is less than or equal to EAR, and EAR is less than or equal to MAXR are not true. This high execute violation signal is applied to a one-legged AND gate 550 which in turn is applied to the input terminal of two-legged AND gate 553 via amplifier 552. When an execute violation interrogate micro-operation signal AJEEVA is applied as another input of two-legged AND gate 553, this gate is enabled which in turn generates the execute violation exception via amplifier 554. The other method by which the execute violation exception is generated by the execute violation hardware 511 is when the execute permission bit EP is not set. When this condition is true it is indicated by the seventh bit of UY register 613 being high; this bit is then applied to the input terminal of one-legged AND gate 551 which is applied as a high signal to one input terminal of AND gate 553 via amplifier 552. When the execute violation interrogate micro-operation signal AJEEVA goes high, AND gate 553 is enabled and generates an execute violation exception via amplifier 554.

The write violation exception is also

generated in two ways. It was seen previously how the UMR logic 505 generates a write violation signal when EAR is greater than WR. This write violation signal is applied to one input terminal of AND gate 545. AND gate 545 is enabled when its second input terminal goes high thus generating a write violation exception through amplifier 547. The second input terminal of AND gate 545 goes high when AND gate 542 is enabled. AND gate 542 is enabled when the input signals applied to its input terminals are high. One input signal is high when UWVIF flop 541 is low which in turn applies a low signal to the input terminal of inverter 543 which in turn applies a high signal to one input terminal of AND gate 542; the other input signal is high when the write violation interrogate micro-op signal AJEWVA is high and this happens when it is desired to interrogate a procedure for the write violation exception. (Flip-flops URVIF, URNIF, and UWVIF are set low when any interrupts or software occurs). (UWV2F, URV2F, and URN2F flip-flops are utilized to store back-up excess checking information for ring checking). The other method for generating a write violation exception is when the write permission bit WP is not set. This condition is indicated by bit 6 of UV register 613 being high. When this condition exists and the high signal (i.e. the sixth bit of UV register) is applied as one input of AND gate 546 and the interrogate signal

AJEWVA is high and applied as another input of AND gate 546, then AND gate 546 is enabled and a write violation exception occurs via amplifier 547.

Logic circuitry 591 comprised of flip-flops 532 and 533 in conjunction with amplifier 530 and AND gate 531 and inverter 530A permit the formation in register UM 502 of the maximum value of ring number (i.e. EAR) under control of a splatter instruction subcommand (not described herein) from the instruction fetch unit IFU. Assuming URNIF flip-flop 532 is set to logical 0 whereas URN2F flip-flop 533 is set to logical 1, then during the execution of the splatter subcommand, input terminal 531A of AND gate 531 will be high; therefore if flip-flop 532 is low (logical 0) then the signal will be inverted by inverter 530A and AND gate 531 will be enabled. Hence the maximum value of the contents of UP register 501 or bits 2 and 3 of logic vector UBS 606 will be strobed into UM register 502. Conversely if flip-flop 532 is a logical 1, then the contents of UM register 502 is not changed via the above mentioned sources and the EAR derived in UM register 502 via the addressing process of indirection is the one utilized. Flip-flop

533 is the back-up store for the EAR of address-syllable 2 when utilized.

Referring now to Figures 7 and 8 and Figure 5 there is a correspondence wherein the detailed logic for hardware in Figure 5 is shown in Figures 7 and 8 as follows: Figure 7a and UW register 504; Figure 7b and UV register 503; Figure 7c and block 590; Figure 7d and block 591; Figure 7e and block 592; Figure 7f and UP register 501; Figure 7g and UO register 512; Figure 7h and UM register 502; Figure 8a and UWV logic 506; Figure 8b and UEP logic 507; and Figure 8d and UMR logic 505.

Referring to Figure 7a, the UW register 504 is comprised of two flip-flops 715a and 720a respectively, each flip-flop capable of holding one bit of information of the UW register. Coupled to flip-flop 715a are 4 AND gates 711a—714a which are OR'ed together, with each gate (except gate 713a) having two input terminals, and with at least one signal applied to each input terminal. AND gate 714a has one of its input terminals coupled to the set terminal OW00010 of the flip-flop 715a. Flip-flop 715a is also coupled to the terminal H27 for receiving from a clock a timing signal called a PDA signal. Flip-flop 720a coupled to AND gates 716a—719a which are OR'ed together. One input terminal of AND gate 716a is coupled to an input terminal of AND gate 711a; one input terminal of AND gate 717a is coupled to one input terminal of AND gate 712a and one input terminal of AND gate 719a is coupled to an input terminal of AND gate 714a, whereas the other input terminal of AND gate 719a is coupled to the set terminal UW00110 of the flip-flop 720a. Flip-flop 720a is also coupled to the H27 terminal for receiving PDA pulses.

AND gates 701a—704a are OR'ed together each having their output terminal coupled to the input terminal of inverter 705a. AND gate 706a is coupled to amplifier 708a; whereas AND gate 707a is coupled to amplifier 709a; one input terminal of AND gate 706a is coupled to one input terminal of AND gate 707a. The output terminal of inverter 705a is coupled to one input terminal of AND gate 714a and 719a; the output terminal of amplifier 708a is coupled to the input terminal of AND gate 713a and the output terminal of amplifier 709a is coupled to the input terminal of AND gate 718a.

The signals applied to the inputs of AND gates and the signals derived as outputs from amplifier, inverters, or flip-flops are designated by letters forming a special code. Since both data signals and control signals are either applied or derived there are two codes, one code for the control signals and one code for the data signals.

The code for the control signals are previously described in detail and is summarized here. Briefly the first two characters of a control signal indicate the destination of data to be transferred; the third character indicates whether a full or partial transfer is to be effected with the letter F indicating full transfer and any other character indicating a partial transfer; the fourth and fifth character indicates the source of the data, and if the source is identified by more than two letters only the last two letters need be used; the sixth and seventh characters are usually numerals and indicate whether the signal is high or low i.e. an odd numeral in the sixth position indicates assertion and an even numeral in the sixth position indicates negation; the seventh position indicates whether this is the first, second, third, etc. level of occurrence of the signal. Data, on the other hand, is indicated differently. The first three characters of data indicates the source of the data, the fourth and fifth characters which may be numerals indicate the bit positions where the data is located in the source, and the sixth and seventh position are similar to the control signals in that they indicate whether the signal is high or low and the level of occurrence of the signal. Generally the format itself indicates whether the signal is a control signal or a data signal and by reference to Figures 5 and 6 the source and destination may be determined. There are exceptions to this general rule and they will be spelled out in the specification, and addendum.

As an example of this convention it will be noted on Figure 7a that the following signals are control signals: UWFAB11, UWFAB10, UW9QA10. The following signals are data signals UAB3410, UAB3210, UAB3510, UAB3310, QA00110, and QA00010. The following signals are exception PDARG10 is a timing signal whose source is the PDA clock; UWHOL10 is a hold signal for holding the information in the flip-flops 715a and 720a UW0BK10 and UW1BK10 are back-up logic whose main function is to extend the input capability of flip-flops 715a and 720a by connecting the UW register which is in fact formed by flip-flops 715a and 720a, to bit zero and bit 1 represented by flip-flops 715a and 720a respectively; and finally USCLR10 is the clear signal for clearing and setting the flip-flops to zero.

As an illustration of the above mentioned convention herein adopted the signal UWFAB11 applied to the input of one-legged AND gate 702a is a control signal which transfers data (bits 34 and 35) contained in UAB associator buffer 611 (the U in the signal has been omitted) to UW register 504 and is a full transfer to the

UW register 1; the odd number indicates the signal is assertion. Signal UWFAB10 applied to the input of one-legged AND gate 703a is a control signal with the same source and destination as the signal applied to AND gate 702a except that bits 32 and 33 of UAB are transferred to UW register. The signal UW9QA10 applied to one-legged AND gate 704a is also a control signal wherein data is transferred from QA bus 614 to the UW register and may be a partial transfer. The signal QA00010 applied to AND gate 706a is a data signal where data is on QA bus 614 (the third position is not herein utilized since the first two positions adequately describe where the data is) and this data signal represents the bit identified as 00 on QA bus 614. The signal QA00110 is similar to the previous signal except the data identified by this signal is the data on position 01 of the QA bus 614. Thus by utilizing this convention and Figures 5 through 9 the ring protection hardware is fully defined and may be easily built by a person of ordinary skill in the computer art.

Referring to Figure 7b there is shown the detailed logic block diagram for UV register 503. Signal UVHOL10 is a hold signal for UV register 503 which is generated via inverter 703b when none of the one-legged AND gates 701b—708b has a high signal applied to it. UVHOL10 signal is applied to AND gate 723b and causes information stored in the UV register 503 to be held therein. Signal UVHOL1E coupled to the input of AND gate 704b and to the outputs of AND gates 705b—708b extends the number of control signals that may generate the hold signal UVHOL10. Signal UV0BK10 coupled to the outputs of AND gates 710b—713b and to the input of AND gate 722b is also utilized to extend the number of inputs signals that may be applied to flip-flop 724b. Signal UV1BK10 coupled to the outputs of AND gates 716b—718b and to the input of AND gate 727b similarly extends the number of input signals that may be applied to flip-flop 729b.

Referring now to Figure 7g there is shown the detailed logic block diagram of UO register 512. AND gates 701g—704g are OR'ed together and their output is applied as an input to inverter 705g. AND gates 706g—709g are also OR'ed together and their outputs are coupled to flip-flop 710g. Also one input of AND gate 709g is coupled to the U000010 terminal of flip-flop 710g. AND gates 711g—714g are also OR'ed together and are similarly coupled to flip-flop 715g. It will be noted also that an input of AND gate 706g is coupled to an input of AND gate 711g; an input of AND gate 707g is coupled to an input of AND gate 712g and an input of AND gate 709g is coupled

to an input of AND gate 714g. The UOHOL10 signal generated by inverter 705g is also coupled to an input of AND gate 709g and 714g and is utilized to hold information in the UO register 512. X00 represents a ground, whereas XNU means unused input.

Figure 7f is a detailed logic block diagram of UP register 501. It is similar to Figure 7g described supra except that different signals from different destinations and different sources are applied.

Referring now to Figure 7h there is shown the detailed logic block diagram of UM register 502. AND gates 701h—704h are OR'ed together to produce the UMHOL10 hold signal via inverter 705h. AND gates 706h—709h are OR'ed together and are coupled to the input of AND gate 704h in order to extend the range of signals that may be applied to produce the UMHOL10 hold signal. Similarly AND gates 711h—714h are OR'ed together and coupled to the input of AND gate 723h in order to extend the range of signals that may be applied to flip-flop 730h; and also AND gates 716h—719h are OR'ed together and are coupled to the input of AND gate 727h in order to extend the range of signals applied to flip-flop 731h. A line 740h for applying the PDA signals to flip-flop 730h and 731h is coupled at point 734h and 735h respectively. The input of AND gate 703h is also expanded to provide two further inputs URN1F00 and IRNUM10 by coupling the output of amplifier 733h to the input of AND gate 703h.

Referring now to Figures 7c—7e there is shown detailed logic block diagrams of write exception control logic 590, IFU subcommand control logic 591, and read violation exception control logic 592 respectively. Referring first to Figure 7c there is shown flip-flops 705c and 710c which correspond to flip-flops 541 and 540 respectively. Under a micro-operation URW2F10 subcommand the information in flip-flop 710c is transferred to flip-flop 705c. The UWV1H10 hold signal is utilized to hold the information transferred to flip-flop 710c, whereas the UWV2H10 signal is utilized to hold the information transferred to flip-flop 705c. Similarly in Figure 7d information is transferred from flip-flop 710d to flip-flop 705d under micro-operation signal URNSW10, and in Figure 7e information from flip-flop 710e is transferred to flip-flop 709e under control of micro-operation signal URW2F10.

Referring now to Figures 8a, 8b and 8d there is shown detailed logic block diagrams of UWV logic 506, UWEP logic 507, and UMR logic 505 respectively. Referring first to Figure 8a there is shown logic for generating a high signal when one

of the test conditions 510 is true and also for generating the execute violation signal when the contents of UW register is less than or equal to the contents of UM register is less than or equal to the contents of UV register is not true. When the signal UWLEV10 is generated it indicates that the contents of UW register 504 is less than or equal to the contents of UV register 503. The logic for generating this signal was derived pursuant to the following Boolean expression:

$$X_1 = \overline{(BCD)} + (AB\overline{D}) \times (\overline{AC})$$

Where  $X_1$  represents the output of amplifier 805a and the various letters of the expression represent different input terminals of AND gates 801a—804a.

An indication that the contents of UV register 503 is greater than or equal to the contents of UM register 502 is had when UVGEM10 signal is generated. This signal is generated via inverter 820a in response to various inputs on AND gates 816a—819a which are OR'ed together and coupled to the input of inverter 820a. The logic for generating the UVGEM10 signal is made pursuant to the following Boolean expression:

$$X_2 = \overline{(BCD)} + (AB\overline{D}) + (\overline{AC})$$

An indication that the contents of UM register 502 is greater than or equal to the contents of UV register 503 is indicated by generating signal UMGEV10 via inverter 810a in response to the various inputs of AND gates 806a—809a which are OR'ed together. The logic for generating this signal is derived from the following Boolean expression:

$$X_3 = \overline{(BCD)} + (AB\overline{D}) + (\overline{AC})$$

(Wherein  $X_3$  is the generated output signal).

Similarly the UVEQM10 signal is generated pursuant to the following Boolean expression:

$$X_4 = (\overline{AC}) + (\overline{AC}) + (B\overline{D}) + (\overline{BD})$$

Generation of the UVEQUM10 signal indicates that the contents of the UV register 503 is equal to the contents of the UM register 502.

The generation of the UMGEV10 signal indicates that the contents of the UM register 502 is greater than or equal to the contents of the UW register 504 and is generated pursuant to logic having the following Boolean expression:

$$X_5 = \overline{(BCD)} + (AB\overline{D}) + (\overline{AC})$$

Generation of the UMGTW10 signal indicates that the contents of UM register 502 is greater than the contents of UW register 504 and this signal is generated by logic defined by the following Boolean expression:

$$X_6 = (AB\overline{D}) + \overline{C}(B\overline{D} + A)$$

The generation of the UWGMV00 signal indicates that the contents of UW register less than or equal to the contents of UM register less than or equal to the contents of UV register is not true. It is obtained when the UVGEM10 signal indicating that the contents of UV register is greater than or equal to the contents of the UM register, and the UMGEV10 signal indicating that the contents of the UM register is greater than or equal to the contents of the UW register are both high.

Referring now to Figure 8b a UMEQP10 signal is generated by logic derived from the following Boolean expression:

$$X_7 = (\overline{AC}) + (\overline{AC}) + (B\overline{D}) + (\overline{BD})$$

When this signal is high it indicates that the contents of UM register 502 is greater than the contents of UP register 501.

Referring to Figure 8d there is shown the detailed logic block diagram for performing the operations of UMR logic 505 shown on Figure 5. One of the operations of this logic is to determine the maximum value of the contents of UP register 501 and of bits 2 and 3 of UBS logic 606. In order to do this there must be an indication whether contents of UP is less than the contents of UBS or the contents of UP is greater than the contents of UBS. The generation of UPBEB10 signal indicates that the contents of UP register 501 is less than or equal to bits 2 and 3 of UBS logic 606; whereas the generation signal UPGTB10 indicates that the contents of UP register 501 is greater than bits 2 and 3 of UBS logic 606. These signals are generated by logic which has been defined by the following Boolean expression:

$$X_8 = \overline{(BCD)} + (AB\overline{D}) + (\overline{AC})$$

Where  $X_8$  is the output of inverter 805d and the letters of the expression are various inputs of the AND gates 801d—803d.

To illustrate how the maximum value of the contents of UP register and UBS logic may be determined by the output signals UMPB010 and UMPB110 of amplifier 814d and 817d respectively, assume first that the contents of register UP are less than or equal to bits 2 and 3 of UBS logic because bit 2 is 1 and bit 3 is 1 whereas UB register

contains 01. This is indicated by the signal UPLEB10 being high and the signal UPGTB10 being low since it is the inverse of signals UPLEB10. This high UPLEB10 signal is applied to one input of AND gate 813d and also one input of AND gate 806d. If bit 2 of UBS logic is a 1 as indicated by signal UBS0210 then AND gate 813d is enabled and signal UMPB010 goes high and indicates that bit 2 on UBS logic is a 1. Moreover if bit 3 of UBS logic is a 1 indicated by input signal UBS0310 being applied as another input of AND gate 816d then AND gate 816d is enabled and signal UMPB110 is high or a 1. Therefore under the assumed conditions where bits (2, 3) UBS logic is greater or equal to the contents of UP register the maximum value of the two quantities is in UBS, and its number is binary 11 or decimal 4. Hence it is seen how a comparison is first made to determine which hardware contains the maximum, and then a determination is made as to the value of that maximum. By similar analysis one may see how the value of the UP register may be determined by signals UMPB010 and signals UMPB110 when the contents of UP register is greater than the second and third bit of UBS logic. Similarly the maximum value of UM register 502 or UV register 503 may be determined by signals UVGEM10 and UMGTV10 respectively, when UV register 503 is greater than or equal to UM register 502, and conversely when UM register 502 is greater than UV register 503.

Referring now to Figures 9a—9i a legend of symbols utilized in Figures 7 and 8 is shown. Figure 9a shows the symbol when there is a connection internally within the logic board. Figure 9b illustrates an output pin connection. Figure 9c indicates an input pin connection and is generally a source outside of the logic board illustrated. Figure 9d is the symbol utilized for an AND gate. Figure 9e is the symbol utilized for an amplifier; whereas Figure 9f is the symbol utilized for an inverter. Figure 9g illustrates three AND gates 901g—903g that are OR'ed together thus causing output 904g to go high when any one of AND gates 901g—903g is high. Figure 9h shows the symbol of a flip-flop having a 00 reset terminal and a 10 set terminal. A PDA line supplies the clock pulse for causing the flip-flop to switch states when other conditions are present on the flip-flop. Figure 9i represents a micro-operation control signal.

In order to enforce the ring protection scheme between procedures executing in different rings, the invention employs push-down stacks for its procedure linkage mechanism wherein a portion of each stack called a stack frame is dynamically

allocated to each procedure. Different stack segments are used for each ring with one stack segment corresponding to one ring. Thus when a procedure is executed in ring RN its stack frame is located in the RN stack segment. Referring to Figure 10 there is shown three stack segments 1001—1003, with each stack segment having stack frames S1—S3 respectively. Ring 3 is assigned to stack segment 1001, ring 1 assigned to stack segment 1002 and ring 0 is assigned to stack segment 1003. Within each stack segment there is a procedure 11 associated with stack frame S1 of segment 1001, a procedure P2 associated with stack frame S2 of stack segment 1002 and a procedure P3 associated with stack frame S3 of stack segment 1003. The segmented addresses (i.e. segment number and segment relative address SEG, SRA) of the first bytes of the stack segments for rings 0, 1 and 2 respectively are located in stack base words SBW0—SBW2 respectively which are in turn located in process control block 104. Since the ring 3 stack segment can never be entered by an inward call (i.e. from a ring higher than ring 3) its stack starting address is not needed. Each stack frame S1, S2, S3 is divided into a working area 1005, 1006, 1007 respectively; an unused portion 1008, 1009, 1010, which is utilized for alignment purposes; a register saving area 1011, 1012, and 1013; and a communication area 1014, 1015, and 1016 respectively. The working area is utilized by its procedure as needed and may contain material required by the process such as local variables, etc. The saving area of the stack frame is utilized to save the contents of various registers such as the status register, the T-register and the instruction counter contents ICC. The communications area stores information which is needed to pass parameters between procedures. Prior to a call to a given procedure the user saves those registers he wishes saved and moreover loads into the communication area the parameters to be passed to the called procedure. When the call is made, the hardware saves the contents of the instruction counter and other specified registers to facilitate a return from the called procedure. Each procedure call creates a stack frame within a stack segment and subsequent procedure calls create additional frames. Hence a stack is created and consists of a number of contiguous parts called stack frames which are dynamically allocated to each procedure. These stacks reside in stack segments. Generally the first stack frame is loaded into the beginning of the segment and succeeding frames are loaded after it. The last frame loaded is considered the top

of the stack. A T-register 114 on Figure 1, locates the top of the stack for the currently active process. A procedure such as for example P1 which is executing in ring 3 may call a procedure P2 executing in ring 1 which in turn calls a procedure P3 which is now executing in ring 0. As each procedure is called it creates within its ring stack segment a stack frame (i.e. defining the environment for the procedure execution) and the T-register 114 is loaded which gives the address of the top of the stack for the current active process. The procedure P1 (as previously assumed) may call procedure P2 which in turn may call procedure P3 and since these calls are from a higher ring number to a lower ring number a ring crossing entailing an inward call is required and is accomplished in a manner to be described infra. During each change of procedure the necessary registers and parameters are saved in order to facilitate a return from the called procedure.

A procedure is always accessed through a procedure descriptor 1110 by means of the ENTER PROCEDURE INSTRUCTIONS. The format of the ENTER PROCEDURE INSTRUCTION 1100 is shown on Figure 11a. The operation code (OP) 1101 occupies bit positions 0 through 7. The complementary code 1102 is a one bit code and occupies bit position 8 to 9; if the complementary code is set to logical 1 the instruction is ENT, whereas if the complementary code is logical 0 the instruction is ENTSR and the base register must be base register 0 (BRO). The address syllable AS 1104 occupies bit positions 12 thru 31 and provides the address syllable AS of the procedure descriptor 1110. When an ENTER PROCEDURE INSTRUCTION requires a ring crossing a gating procedure descriptor 1120 is obligatorily accessed. This is indicated by the GS field 1302 of segment descriptor 1301 being set to logical 10. Generally the GS field is set to 10 when one of the ENTER PROCEDURE INSTRUCTIONS is utilized. As described in the application No. 21630/76, Serial No. 1,465,344, the segment descriptor is utilized to point to the base of the segment desired, in this instance the segment 1300 containing gate procedure descriptors GPD 1120. The first word of the segment 1300 containing the gating procedure descriptors (GPD's) is formatted as shown in Figure 11c. The TAG 1121 occupies bit positions 0 and 1 and must indicate a fault descriptor i.e. the TAG field must be set to logical 11. The Caller's Maximum Ring Number CMRN 1122 occupies bit positions 2 and 3, and indicates the maximum ring from which a calling procedure through the gated procedure descriptor GPD is legal. A call

violation exception is generated if the caller's ring number is greater than CMRN 1122. The gated procedure descriptor address boundary GPDAB 1124 occupies bit positions 10 through 31 and it must be greater than the segment relative address SRA (i.e. the GPD's displacement in the segment of procedure descriptors 1300), otherwise an illegal GPD access exception occurs. Thus a gating procedure descriptor GPD is utilized as the first word of the segment containing procedure descriptors and is utilized to determine whether the caller has a right to access the segment via the caller's maximum ring number CMRN and whether or not the procedure descriptor called is within the gating procedure descriptor's address boundary. Once it is determined that there is a legal call to the segment and the caller has a right to enter the segment the address is obtained from the address syllable AS 1104 of enter instruction 1100 and the required procedure descriptor 1110 (see also Figure 13) is accessed. The format of procedure descriptor 1110 is shown on Figure 11b and is comprised of two 32 bit words—word 0 and 1 respectively. Word 0 contains the segmented address 1113 of the entry point EP of the procedure desired. The segmented address, as is the case with the segmented address of any operand, is comprised of the segment number SEG and the segment relative address SRA. Word 0 of the procedure descriptor includes an entry point ring number EPRN 1112 and a TAG field 1111. The value of the TAG is interpreted as follows:

- a. if the TAG contains logical 00 the procedure descriptor is direct;
- b. if the TAG is logical 01 the procedure descriptor is an extended descriptor and includes word 1 making a total of two words;
- c. if the TAG is logical 10 the procedure descriptor is indirect and an illegal procedure descriptor exception occurs; and
- d. if the TAG is logical 11 it is a fault procedure descriptor and an exception occurs.

Word 1 of the procedure descriptor is 32 bits long and is utilized when the TAG indicates an extended descriptor and contains the segmented address of a linkage section whose contents are loaded in base register BR 7 at procedure entry time.

Referring to Figure 12 a portion of the ENT instruction is shown and more specifically that portion which pertains to the ring crossing and ring checking requirements. The ENT instruction is called, 1201 and a comparison is made 1202 wherein the segmented part of the base register BRn is compared to the segmented part of the address of the T register, and if

they are not equal an illegal stack base register 1208 is indicated. If on the other hand they are equal another comparison 1203 is made wherein the 30th bit including the next two bits (i.e. bits 30 and 31) of base register, BRn is compared to 0 and if it is not equal to 0, then once again an illegal stack base register 1208 is indicated. If it is equal to 0 it indicates that the contents of BRn is aligned with respect to the word boundary and another comparison 1204 is performed to determine that the TAG of BRn (i.e. the two bits starting from bit 0) is equal to 0. A TAG having a logical 0 indicates information is accessed via a direct descriptor which is one of the requirements of the ENT instruction. If the TAG (i.e. bits 0 and 1 of BRn) is equal to 0 then the functions stated in flow charts of Figures 14 through 16 are performed (see flow chart Figure 12 block 1205). If these meet the necessary requirements a further check 1206 is made to determine whether the segment relative address of the entry point which was given (SRA<sub>EP</sub>) is even, because instructions start on a half-word boundary. If it is not even then an illegal branch address exception is generated 1209 however if it is legal the ENT instruction is executed 1207 via further steps not shown.

Referring now to the flow charts of the access checking mechanism Figures 14—16, generally the following operations are performed each time the instruction ENTER PROCEDURE is issued:

a. the caller's right to call the callee is checked by first determining from the second word of the segment descriptor the call bracket in which the caller is executing. (The call bracket is determined by taking the minimum ring number from the write ring number field WR and the maximum ring number from the maximum ring number field MAXR).

b. a decision is made about the next process ring number by determining whether the caller is in the same call bracket as the callee, which implies don't do anything; whether the caller is in a call bracket requiring that he make an outward call in which case an exception condition is generated which is handled by a mechanism not described herein; or finally whether the caller is in a call bracket which requires an inward call (i.e. going to a call bracket which requires ring crossing from a larger ring number to a smaller ring number in which case the ring crossing must be at a valid entry point EP and the entry point must be validated).

c. a stack frame is created for the callee (i.e. space in the aforementioned format of the appropriate segment is allocated), and

the stack frame and the stack frame registers are updated;

d. a branch to the entry point of the procedure pointed to by the procedure descriptor is performed.

Referring now to Figure 14 the access checking is started 1401 by obtaining the address syllable AS containing the effective address ring number EAR, the segment number of the procedure descriptor SEG<sub>PD</sub>, and the segment relative address of the procedure descriptor SRA<sub>PD</sub>. Having developed this information the procedure descriptor 1110 is fetched 1403 from (SEG<sub>PD</sub>, SRA<sub>PD</sub>) ignoring access rights to scratch pad memory. The procedure descriptor 1110 will yield the TAG which determines whether the descriptor is direct, extended, indirect, or a fault descriptor; the entry point ring number EPRN; the segment (SRA<sub>EP</sub>) which contains the entry point and the segment relative address (SRA<sub>EP</sub>) of the entry point. The TAG is tested 1404 to determine whether the descriptor 1110 is direct, extended, indirect or a fault descriptor by checking its field in accordance to the code hereinbefore described. Only a direct or extended procedure descriptor is legal. An indirect or fault descriptor is illegal and upon access invokes an exception mechanism not herein described. Once it is determined that a legal procedure descriptor has been accessed the actual call right checking begins at point A 1405.

Referring now to Figure 15 and continuing from point A 1405 the maximum ring number MAXR, the write ring number WR, and the execute permission bit EP of the segment containing the entry points SEG<sub>EP</sub> are fetched; this information is contained in the segment descriptor for the segment containing the entry points (SEG<sub>EP</sub>). The write ring number WR is compared to the maximum ring number MAXR 1503 and if the write ring number WR is greater than the maximum ring number MAXR the segment is nonexecutable and an execute violation exception 1513 occurs. If the write ring number WR is less than or equal to the maximum ring number MAXR then the execute permission bit EP is compared to logical 1 and if the EP bit is not logical 1 then once again an execute violation exception 1513 occurs; however if the EP bit is equal to one the effective address ring number EAR of the calling procedure is maximized with EPRN to give a new EAR<sub>1</sub>—[MAX (EAR, EPRN)] where EAR<sub>1</sub> is the maximum of PRN as found in the instruction counter IC, and all ring numbers in base registers and data descriptors, if any, found in the path which leads to the procedure descriptor. The

effective address ring number  $EAR_2$  is then compared 1506 to the maximum ring number MAXR of the MAXR segment descriptor of  $SEG_{pp}$  which is the maximum ring number at which a procedure may execute. If  $EAR_2$  is greater than MAXR the procedure call is an inward call which requires that the procedure be entered by a valid entry point and the access checking operation branch to point B 1507. The following checking operations are then performed:

- the  $SEG_{pp}$  is checked to determine if it is a legal gate segment; and,
- the caller's maximum ring number CMRN is checked to determine if it is greater than or equal to the effective address ring number EAR of the caller.

If these conditions are not true then an illegal gate segment exception 1603 or call violation exception 1615 occurs.

Referring now to branch point B 1507 of Figure 16 the first check 1602 that is made is to determine whether or not the segment which contains the procedure descriptors is a gate segment. This is done by examining the Gating/Semaphore field GS of the segment descriptor pointing to the segment of procedure descriptors, to determine if it is set to logical 10. If the GS field of the segment descriptor of the segment containing procedure descriptors is set to 10 it is then a gate segment and the first word of the segment containing procedure descriptors is a gated procedure descriptor GPD 1120 of Figure 11C and Figure 13. The first word 1120 of the segment containing procedure descriptors is then fetched from address  $SEG_{pp}$ , 0 ignoring access rights to scratch pad memory. It will be noted that the TAG field of the first word 1120 of the segment containing procedure descriptor  $SEG_{pp}$  1300 must be a logical 11 (Figure 13) which indicates it is a fault descriptor. Moreover the MBZ field must be set to zero. These conditions are checked by hardware/firmware (arithmetic logic unit) stop 1605 and if these conditions do not hold an illegal gate segment exception 1603 results. However if these conditions do hold a check 1606 is further made to determine that the segment relative address of the procedure descriptor  $SRA_{pp}$  1110 is a multiple of 8. If the condition of step 1606 does not hold an illegal system object address exception 1613 results otherwise the next step 1607 is performed. Step 1607 checks to determine whether or not the segment relative address of the procedure descriptor  $SRA_{pp}$  is within the address boundary GPDAB 1124 of the gated procedure descriptor 1120; if it is not within that address boundary it is an illegal procedure descriptor and an illegal GPD gated procedure descriptor access exception 1614 occurs. However if it is within the address boundary of the gated procedure descriptor (i.e.  $SRA_{pp}$  is less than GPDAB) then the caller's right to call the callee is checked 1608. This is performed by comparing the effective address ring number  $EAR_2$  to the caller's maximum ring number CMRN 1122 as found in the first word 1120 of the segment of procedure descriptors 1300. If  $EAR_2$  is greater than the caller's CMRN a call violation exception 1615 occurs which indicates that the caller in this particular instance has no right to legally call inward i.e. from a higher ring number to a lower ring number. On the other hand if  $EAR_2$  is equal or less than CMRN, then the inward call is legal and a check is made 1609 to determine that the process ring number PRN which is the current process ring number found in the instruction counter IC just before the call was made is less than the maximum ring number MAXR of  $SEG_{pp}$ ; and if it is the accessing mechanism branches to point C 1508, otherwise a new process ring number NPRN is calculated and set to a maximum ring number MAXR 1611. Generally the effective address ring number  $EAR_2$  is the same as the process ring number PRN of the caller. Sometimes however, in cases where it is necessary to give maximum assurance that the caller will not be denied access to a given segment the  $EAR_2$  is greater than the PRN. In those cases 1 RN is forced to take the value of  $EAR_2$  in order to make sure that the call is returned to the maximum ring number upon an exit. To this point it will be noted that this checking mechanism was invoked because the  $EAR_2$  was greater than the MAXR hence greater than the top of the call bracket of the procedure and hence an inward call was necessary which necessitated going through a valid gate, and the mechanism included these gating checks. By branching back to C 1508 (Figure 15) a further check 1509 is made to determine then that the process ring number PRN is greater than the write ring number WR of  $SEG_{pp}$  which in this context is the minimum ring number at which a procedure may execute. If the write ring number WR is greater than the process ring number PRN an outward call exception 1514 occurs. However if WR is less than or equal to PRN the call is legal and NPRN is set to PRN 1510.

Having made the above checks the inward call is made, and after performance of the desired operation a return back to the original point of the program in execution is made by the EXIT INSTRUCTION. During the ENTER INSTRUCTION the instruction counter IC

was saved in the saving area of the caller's stack frame before making the call. Moreover the caller's ring number was also saved during the ENTER INSTRUCTION and this was saved in base register 0 BRO.

The format of the EXIT INSTRUCTION 1130 is shown on Figure 11D. The operation code OP 1131 is found in bit positions 0—7 and the complementary code C 1133 is found in bit positions 12—15. The complementary code allows other instructions to use the same 8 bit op code. The MBZ field 1132 in bit positions 8—11 must be 0 otherwise an illegal format field exception occurs. (BRO is generally a pointer to the communications area of the caller's stack frame).

In performing the EXIT INSTRUCTION it is necessary to perform predetermined checks in order to ascertain that the caller didn't change his image which would permit him to operate at a different privilege than was intended. Referring to Figure 17 the first check performed 1701 is to determine if the TAG of the instruction counter content (ICC) indicates a direct descriptor. A logical 00 in the TAG field indicates that it is direct if it is not an illegal stack data exception 1702 occurs, whereas if it is equal to 0 the ring field in the instruction counter content ICC is set to the new process ring number NPRN 1703. This sets the new process ring number NPRN to what it used to be when the call was first made. However further checks are made in order to ascertain that there was no further cheating. Hence the base register 0 ring number located at bit position 2 and extending for 2 bit positions from and including bit position 2 must be equal to the new process ring number NPRN 1704. (It will be recalled that when the ENTER INSTRUCTION was called the ring number of the caller before the call was made was stored in bits 2 and 3 of base register 0 (BRO). If check 1704 indicates that the new process ring number NPRN is not

equal to the ring number in bit positions 2 and 3 of the base register 0 (BRO) an illegal stack data exception 1702 occurs. The next check 1705 determines whether an inward or an outward return must be performed. Since an inward call was previously performed an outward return is implied in order to reach the original point from which the procedure was called. Moreover since the invention does not permit an outward call there is never a necessity to return inward. Hence the new process ring number NPRN is compared to the process ring number PRN 1705, and if NPRN is less than PRN an inward return is implied and an inward return exception 1706 is generated. However if check 1705 is passed successfully (i.e. NPRN is greater or equal to PRN) then a check is made to determine that a return is made to the segmented address SEGr that called the procedure and a return to the call bracket of the calling procedure is made and moreover that the execute bit EP is set. This is performed by fetching the segment descriptor SEGr of the calling procedure 1707 and making checks 1709, 1711, 1712. In performing checks 1709, 1711, 1712, check 1709 and 1711 determine that the new process ring number NPRN is greater than the minimum ring number WR but less than the maximum ring number MAXR (i.e. that the ring number is in the call bracket of the calling procedure where it should be). Finally check 1712 makes sure that the execute permission bit EP is set to 1. Thus a full cycle is concluded a call was performed via an ENTER INSTRUCTION; the required operation or processing was performed via the called procedure; then a return via an EXIT INSTRUCTION to the calling procedure was performed.

Having shown and described the preferred embodiment of the invention, those skilled in the art will realize that many variations of modifications can be made to produce the described invention and still be within the scope of the claimed invention.

#### Glossary of Terms

JOB—The job is the major unit of work for the batch user. It is the vehicle for describing, scheduling, and accounting for work he wants done.

JOB STEP—A smaller unit of batch work. It is generally one step in the execution of a job consisting of processing that logically belongs together.

TASK—The smallest unit of user-defined work. No user-visible concurrency of operation is permitted within a task.

PROGRAM—A set of algorithms written by a programmer to furnish the procedural information necessary to do a job or a part of a job.

PROCESS GROUP PLEX—The system's internal representation of a specific execution of a job.

PROCESS GROUP—A related set of processes, usually those necessary for performance of a single job step.

PROCESS—The controlled execution of instructions without concurrency. Its physical representation and control are determined by internal system design or convention.

## Glossary of Terms (cont.)

- PROCEDURE**—A named software function or algorithm which is executable by a computational processor without concurrency. Its physical representation (code plus associated information, invocation, and use are determined by internal system or designed convention).
- LOGICAL PROCESS**—The collection of hardware resources and control information necessary for the execution of a process.
- ADDRESS SPACE (SEGMENTATION)**—The set of logical addresses that the CPU is permitted to transform into absolute addresses during a particular process. Although a processor has the technical ability of addressing every single cell of timing memory, it is desirable to restrict access only to those cells that are used during the process associated with the processor.
- LOGICAL ADDRESS**—An element of the process address space such as for example segment number SEG and Displacement D.
- BASIC ADDRESS DEVELOPMENT**—A hardware procedure which operates on a number of address elements to compute an absolute address which is used to refer to a byte location in core.
- PROCESS CONTROL BLOCK**—A process control block PCB, is associated with each process and contains pertinent information about its associated process, including the absolute address of tables defining the segment tables the process may access.
- J. P. TABLES**—A collection of logical addresses for locating a process control block associated with a process.
- SEG<sub>PD</sub>**—The segment which contains the procedure descriptor.
- SEG<sub>EP</sub>**—The segment which contains the entry point, as found in the procedure descriptor.
- PRN**—The process ring number, found in the instruction counter IC just before the call, or calculated by the ENTSR instruction.
- EAR**—The effective address ring number which is the maximum of:  
(a) the process ring number PRN as found in the IC; or  
(b) all ring numbers in the base register and data descriptors (if any) found in the path which leads to the procedure descriptor from the call instruction, including the entry point ring number EPRN located in the procedure descriptor itself.
- MAXR**—The maximum ring number at which a procedure may execute; MAXR is found in the segment descriptor of SEG<sub>EP</sub>.
- WR**—The minimum ring number at which a procedure may execute; WR is found in the segment descriptor of SEG<sub>EP</sub>.
- EP**—Execution permit bit found in the segment descriptor of SEG<sub>EP</sub>.
- CMRN**—The caller's maximum ring number, as found in the first word of the segment SEG<sub>PD</sub> if this segment is identified as a gate segment (i.e. with the code "gate" set).
- NPRN**—New process ring number.
- EPRN**—Entry point ring number (found in the process procedure descriptor).

## Addendum

Signal Name	Type	Function
(1) WSCLR	Control	Clears register to which it is connected.
(2) PDARG	Control	Clock Signal PDA.
(3) PDURGIT	Connecting	Pin connected to PDA at one end and resistor at the other.
(4) UWOBK	Connecting	Expands inputs to UW register.
(5) UWHOL	Control	Holds information in register to which it is connected.
(6) UW1BK	Control	Same as UWOBK but is connected to different input terminal of UW register.
(7) UW00000		Reset terminal of one flip-flop of register UW.
(8) UW00010		Set terminal of flip-flop of register UW.
(9) UW00100		Same as 7+8 but different flip-flop.
UW00110		
(10) UVSPS	Control	Spare Control Input.

## Addendum (cont.)

	Signal Name	Type	Function
	(11) UVSPD	Data	Spare Data Input.
5	(12) UVOBK	Expander	Same as UW0BK and UW1BK, but it connects different registers and gates.
	(13) UV00000		Same as UW00000, UW00010, UW00100, UW00110, but applies to flip-flop UV.
	UV00010		
	UV00100		
	UV00110		
10	(14) UWV1S	Control	Control input for UWV1F.
	(15) UWV1D	Data	Data input for UWV1F.
	(16) UWV2F	F/F	Write control flip-flop.
	(17) UWV1S	Control	Control unit for UWV1F, UWV2F.
	UWV2S		
15	(18) UWV1D	Data	Data input for UWV1F.
	(19) UWV1H	Control	Hold UWV1F flip-flop.
	(20) UWV1C	Control	Clear UWV1F.
	(21) UWV2C	Control	Clear UWV2F.
	(22) URN1S	Control	Control inputs for URN1F, URN2F.
	URN2S		
20	(23) URN1D	Data	Data Input for URN1F.
	(24) URNSW	Control	Transfer URN1F to URN2F and URN2F to URN1F.
	(25) URN2F	F/F	Control loading max (UP, UBS2, 3 to UM).
25	(26) URN1H	Control	Hold URN1F flip-flop.
	(27) URN2C	Control	Clear URN2F.
	(28) URW1S	Control	Control inputs for URV1F, URV2F.
	URW2S		
	(29) URW1D	Data	Data Input for URV1F.
30	(30) URV2F	F/F	Read control flop.
	(31) XNU		Indicates terminal not used herein.
	(32) XO0		Grounded Input.

## WHAT WE CLAIM IS:—

1. An internally programmed data processing apparatus CPU having a virtual memory system, and being responsive to internally stored instruction words for processing information and having stored in said virtual memory system a plurality of different types of groups of information each information group-type associated with an address space bounded by a segment having adjustable bounds, and comprising means for protecting the information in said-virtual memory system from unauthorized users by restricting accessibility to the information in accordance to levels of privilege, said means comprising in combination with an access checking mechanism;
- (a) first means arranged in operation to store in said virtual memory system at least one segment table comprising a plurality of segment descriptors with each segment descriptor being associated with a predetermined one of said segments and each segment descriptor having a predetermined format containing an access information element and a base address element in predetermined positions of said format, said base address element being used for locating in said virtual memory system the starting location of a selected one of said segments, and said access information element for specifying the minimum level of privilege required for a predetermined type of access that is permitted in a selected one of said segments;
- (b) a plurality of second means having a predetermined format, communicating with said first means, arranged to store in a predetermined portion of said second means, a segment number SEG for identifying a segment table and the location of a segment descriptor within said segment table, said second means also being arranged to store in a predetermined other portion of said second means, an offset address within the segment identified by said segment descriptor said offset address locating from said segment base the first byte of a word within said segment;
- (c) third means responsive to an address syllable element of an instruction being executed for addressing one of said plurality of second means;
- (d) fourth means arranged to store a displacement from said address syllable,
- (e) fifth means, communicating with said first, second, third and fourth means, arranged to add the displacement D and said base address to said offset; and,
- (f) sixth means responsive to said access

- information element in a selected one of said segment descriptors, restricting the accessibility to the segment associated with said selected one of said segment descriptors in accordance to the level of privilege and the type of access specified in said access information element, wherein each group-type of information is associated with a predetermined ring number indicative of a level of privilege said level of privilege decreasing as the associated ring number increases comprising means for determining the maximum effective address ring number EAR (i.e. minimum level of privilege) of a selected process to access a selected group of information, said means comprising:
- (a) first means to store first information indicating the maximum ring number RD (i.e. minimum level of privilege) required to read information from said selected group;
  - (b) second means to store second information indicating the maximum ring number WR (i.e. minimum level of privilege) required to write information into said selected group;
  - (c) third means to store third information indicating the maximum ring number MAXR (i.e. minimum level of privilege) required to process information from said selected group; and,
  - (d) fourth means communicating with said first, second and third means, to determine the maximum of the contents of said first, second and third means whereby the effective address ring number EAR is generated.
2. Apparatus according to claim 1, wherein said second means for storing the maximum ring number WR additionally indicates the minimum ring number WR (i.e. maximum level of privilege) required to process information from said selected group.
3. Apparatus according to claim 1 or claim 2, wherein said fourth means to generate the effective address ring number comprises a comparator for comparing binary numbers.
4. Apparatus according to any one of claims 1 to 3 wherein the sixth means restricting the accessibility to the segment includes comparator means, communicating with said second means, to compare the effective address ring number EAR with the write ring number WR, and further including means communicating with said comparator means to generate a write-violation-exception signal when EAR is greater than WR.
5. Apparatus according to claim 4, wherein the sixth means restricting the accessibility to the segment includes seventh means, communicating with said second and third means thereof to compare the maximum ring number MAXR and the write ring number WR with the effective address ring number EAR, and further including eighth means, communicating with said seventh means for generating an execute-violation-exception signal when the MAXR is not equal or greater than EAR which in turn is not equal or greater than WR.
6. Apparatus according to claim 5, wherein in that the sixth means restricting the accessibility to the segment includes ninth means, communicating with said first means, for comparing the effective address ring number EAR with the read ring number RD, and further including tenth means, communicating with said ninth means, to generate a read-violation-exception signal when EAR is greater than RD.
7. Apparatus according to claim 6, wherein in that the sixth means restricting the accessibility to the segment includes eleventh means to store a process ring number PRN of a currently executing process, and also including twelfth means to communicate with said eleventh means, and further including thirteenth means communicating said said twelfth means for overriding said read-violation-exception signal when the effective address ring number EAR is equal to the process ring number PRN of the currently executing process.
8. Apparatus according to any one of the preceding claims wherein the access checking mechanism supervises transfer of control of said CPU from a first selected procedure (i.e. caller) having a first ring number indicative of a minimum level of privilege associated with said caller, to a second selected procedure (i.e. the callee) having a second ring number associated with said callee indicative of a minimum level of privilege associated with said callee, said access checking mechanism comprising
- (a) first means for checking the caller's right to call the callee;
  - (b) second means, communicating with said first means, to compare the caller's ring number to the callee's ring number;
  - (c) third means responsive to said second means to permit a transfer of control of said CPU from said caller to said callee when the ring number of the caller is greater than the ring number of callee (i.e. inward call); and,
  - (d) fourth means also responsive to said second means to deny a transfer of control of said CPU from said caller to said callee when the ring number of said caller is less than the ring number of the callee (i.e. outward call).

9. Apparatus according to claim 8, wherein the access checking mechanism includes a plurality of ring stack-segment means each of said ring stack-segment means having associated with it a ring stack-segment number, indicative of the minimum level of privilege required by a selected one of said procedures to access a selected one of said ring stack segments.
10. Apparatus according to claim 9 wherein there are four ring stack segment means having ring numbers 0 to 3 respectively.
11. Apparatus according to claim 9 or claim 10 wherein the access checking mechanism includes stack-frame-element means associated with selected ones of said procedures, said stack-frame-element means being grouped within said ring stack-segment means in accordance with the ring number of the associated procedure of said

stack-frame-element means, said stack frame element means to save said register of said caller prior to passing control to said callee.

12. Apparatus according to claim 11, wherein the access checking mechanism includes first sub-element means, responsive to said first, second, third and fourth means, for communicating between a selected one of said stack-frame-means in a first ring stack-segment being associated with one ring number, and a selected other of said stack-frame-means in a second ring stack-segment associated with another ring number.
